

# Improving peat depth/soil carbon stock mapping for Scotland

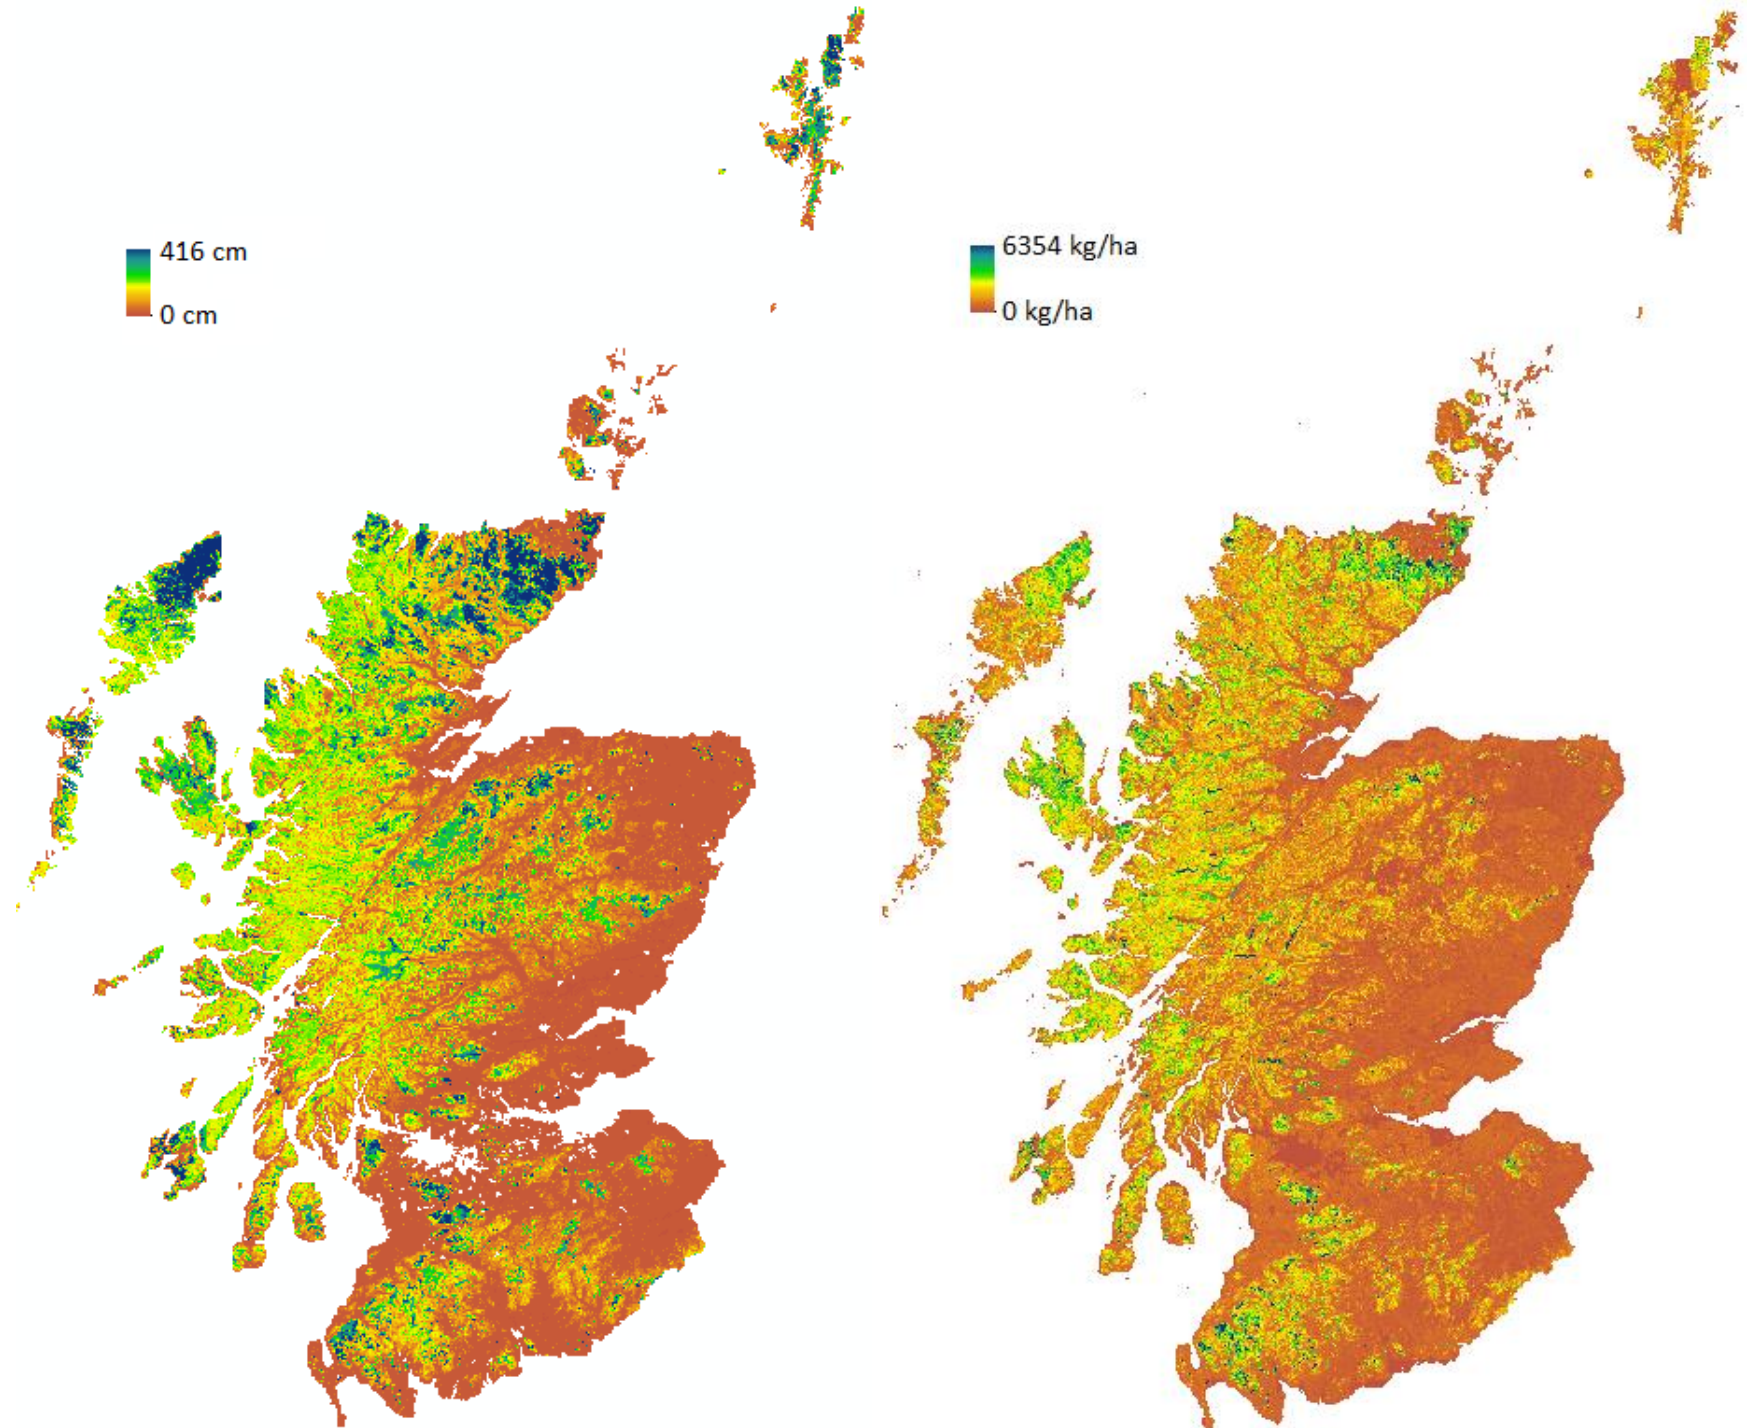

Matt Aitkenhead

The James  
**Hutton**  
Institute

# What we have

- 100 metre resolution maps of peat depth and carbon stock
- Mapped using Scottish Soil Database and early Peatland Action data
- Aitkenhead, M.J., Coull, M.C., 2019. Mapping soil profile depth, bulk density and carbon stock in Scotland using remote sensing and spatial covariates. *European Journal of Soil Science*. 10.1111/ejss.12916

# What do we need?

- Finer spatial resolution
  - 100m not good enough for highly variable landscapes
- Better information 'down the profile'
  - Carbon storage and accumulation at depth
  - C stocks in non-peat soils (e.g. wet grassland)

# How do we do it?

- DSM (Digital Soil Mapping)
- Link soil properties (density and carbon concentration) to soil-forming factors
- Use the model to predict these properties at each location and depth
- Scottish Soils Database has data for >3000 soil profiles

# What do we need?

- Soil forming factor datasets
- At 10 metre resolution
- Topography is the major factor that changes at such small scales
- Climate
- Geology
- Vegetation/land cover
- Remote sensing

# The model works

- Accuracy of bulk density model:  $R^2 = 0.78$
- Accuracy of carbon concentration model:  $R^2 = 0.74$
- Spatial datasets prepared (1.5 TB data)
  - Harmonised grids
  - Rapid access
  - HPC-ready
  - Flexible for inclusion of new remote sensing data

# Maps to be created

- Every 5 cm depth (2.5, 7.5, 12.5 etc...)
- 10 metre spatial resolution
- Bulk density and carbon concentration
  - Allows carbon stock per unit volume to be calculated
  - BD & C also useful for e.g. erosion, crop growth modelling, hydrology etc.
- When density/carbon reach values indicating “not soil”, stop
  - Density  $>1400 \text{ kg m}^{-3}$  OR C  $< 0.1\%$

# Computational requirements

- Significant! (200x previous, which took 2 months on a PC)
- High Performance Computing (>1000 CPU cores)

# Why will this help?

- Small bog areas
- Edges of bogs
- More **accurate** carbon stock assessment
- More **precise** carbon stock assessment
- Better targeting of restoration
- Better understanding of C stock in peat vs non-peat soils

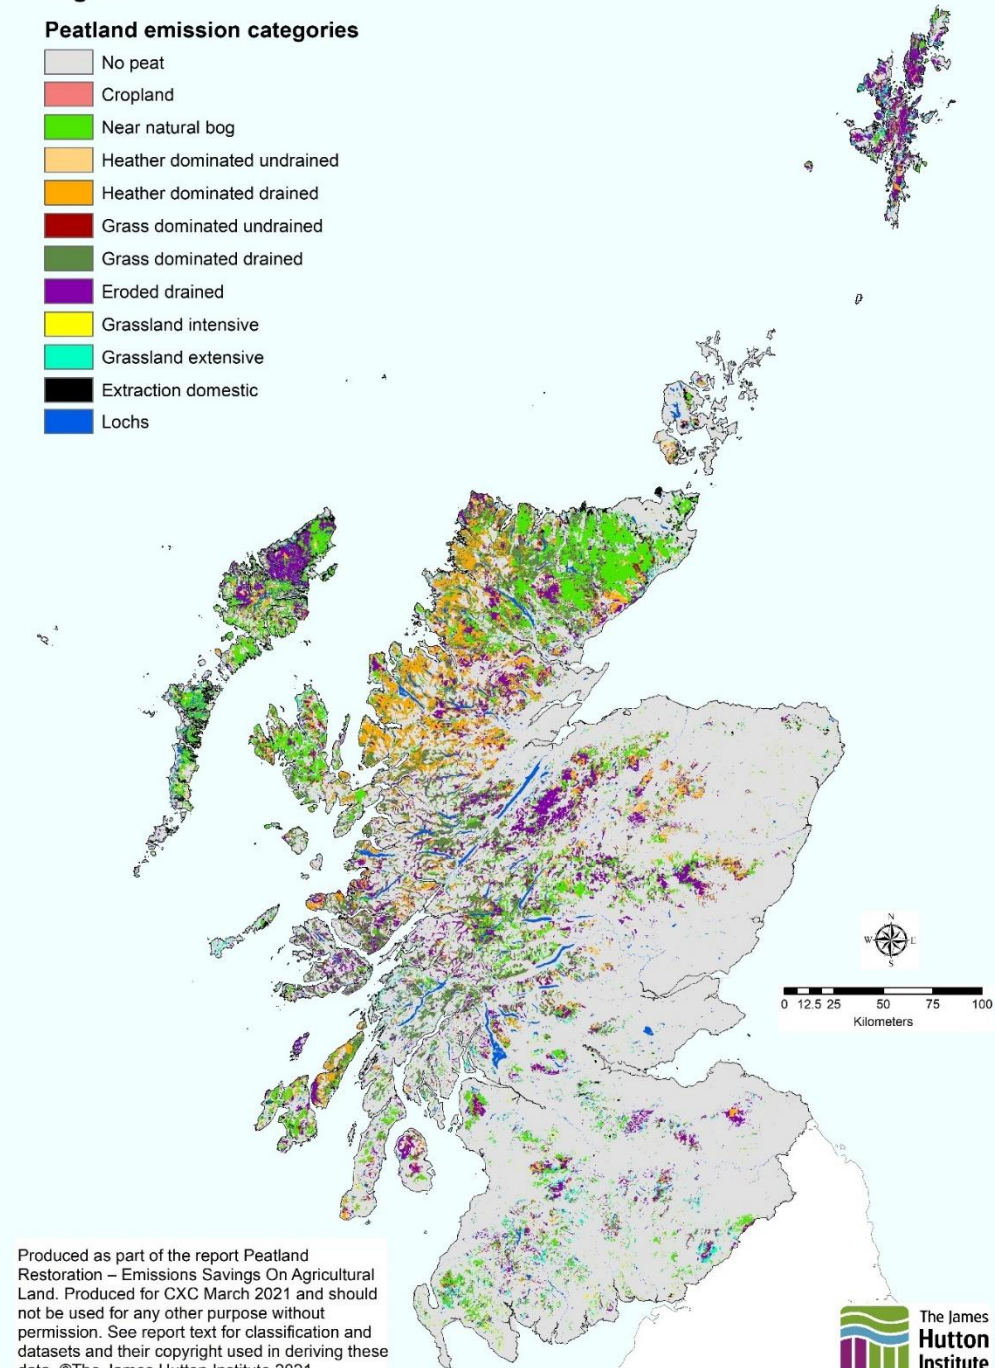

# Why will this help?

- Alignment with land cover/land use maps (10-20 metre scale)
- Topographic/drainage conditions better informed
- Alignment with peat condition mapping (existing and future)
- Baseline data for Tier 3 GHG emissions and restoration monitoring

## Legend

### Peatland emission categories

Grey	No peat
Red	Cropland
Light Green	Near natural bog
Orange	Heather dominated undrained
Dark Orange	Heather dominated drained
Dark Red	Grass dominated undrained
Dark Green	Grass dominated drained
Purple	Eroded drained
Yellow	Grassland intensive
Cyan	Grassland extensive
Black	Extraction domestic
Blue	Lochs
